FORM PTO-1390 (REV. 5-93)		U.S. DEPARTMENT OF COMMERCE PATENT AND TRADEMARK OFFICE	CASE NO. 9185/5
TRANSMITTAL LETTER TO THE UNITED STATES DESIGNATED/ELECTED OFFICE (DO/EO/US) CONCERNING A FILING UNDER 35 U.S.C. 371			U.S. APPLICATION NO. (If known, see 37 C.F.R. 1.5)  <b>09/581949</b> <small>not yet assigned</small>
INTERNATIONAL APPLICATION NO. PCT/US98/27374	INTERNATIONAL FILING DATE 23 December 1998	PRIORITY DATE CLAIMED 29 December 1997	
TITLE OF INVENTION ENERGY MINIMIZATION FOR CLASSIFICATION, PATTERN RECOGNITION, SENSOR FUSION, DATA COMPRESSION, NETWORK RECONSTRUCTION AND SIGNAL PROCESSING			
APPLICANT(S) FOR DO/EO/US Glickman, Jeff B. and Wolman, Abel			
Applicant herewith submits to the United States Designated/Elected Office (DO/EO/US) the following items and other information:			
1. <input checked="" type="checkbox"/> This is a FIRST submission of items concerning a filing under 35 U.S.C. 371			
2. <input type="checkbox"/> This is a SECOND or SUBSEQUENT submission of items concerning a filing under 35 U.S.C. 371			
3. <input checked="" type="checkbox"/> This express request to begin national examination procedures (35 U.S.C. 371(f)) at any time rather than delay examination until the expiration of the applicable time limit set in 35 U.S.C. 371(b) and PCT Articles 22 and 39(1).			
4. <input checked="" type="checkbox"/> A proper Demand for International Preliminary Examination was made by the 19th month from the earliest claimed priority date.			
5. <input checked="" type="checkbox"/> A copy of the International Application as filed (35 U.S.C. 371(c)(2)).			
a. <input type="checkbox"/> is transmitted herewith (required only if not transmitted by the International Bureau).			
b. <input checked="" type="checkbox"/> has been transmitted by the International Bureau.			
c. <input type="checkbox"/> is not required, as the application was filed in the United States Receiving Office (RO/US).			
6. <input type="checkbox"/> A translation of the International Application into English (35 U.S.C. 371(c)(2)).			
7. <input checked="" type="checkbox"/> Amendments to the claims of the International Application under PCT Article 19 (35 U.S.C. 371(c)(3)).			
a. <input type="checkbox"/> are transmitted herewith (required only if not transmitted by the International Bureau).			
b. <input type="checkbox"/> have been transmitted by the International Bureau.			
c. <input type="checkbox"/> have not been made; however, the time limit for making such amendments has NOT expired.			
d. <input checked="" type="checkbox"/> have not been made and will not be made.			
8. <input type="checkbox"/> A translation of the amendments to the claims under PCT Article 19 (35 U.S.C. 371(c)(3)).			
9. <input checked="" type="checkbox"/> An oath or declaration of the inventor(s) (35 U.S.C. 371(c)(4)).			
10. <input type="checkbox"/> A translation of the annexes to the International Preliminary Examination Report under PCT Article 36 (35 U.S.C. 371(c)(5)) and/or amendments under Article 34.			
<b>Items 11. to 16. Below concern other document(s) or information included:</b>			
11. <input checked="" type="checkbox"/> An Information Disclosure Statement under 37 CFR 1.97 and 1.98.			
12. <input type="checkbox"/> An assignment document for recording. A separate cover sheet in compliance with 37 CFR 3.28 and 3.31 is included.			
13. <input type="checkbox"/> A FIRST preliminary amendment.			
<input type="checkbox"/> A SECOND or SUBSEQUENT preliminary amendment.			
14. <input type="checkbox"/> A substitute specification.			
15. <input type="checkbox"/> A change of power of attorney and/or address letter.			
16. <input checked="" type="checkbox"/> Other items or information:			
An Amendment to the Abstract not transmitted by the International Bureau.

otherwise reserves all copyright rights whatsoever.

## APPENDIX

15           An appendix of computer program source code is included and comprises  
22 sheets.

          The Appendix is hereby expressly incorporated herein by reference, and  
contains material which is subject to copyright protection as set forth above.

## BACKGROUND OF THE INVENTION

20           The present invention relates to recognition, analysis, and classification of  
patterns in data from real world sources, events and processes. Patterns exist  
throughout the real world. Patterns also exist in the data used to represent or  
convey or store information about real world objects or events or processes. As  
information systems process more real world data, there are mounting  
requirements to build more sophisticated, capable and reliable pattern recognition  
25           systems.

          Existing pattern recognition systems include statistical, syntactic and neural  
systems. Each of these systems has certain strengths which lends it to specific  
applications. Each of these systems has problems which limit its effectiveness.

Existing pattern recognition systems include statistical, syntactic and neural systems. Each of these systems has certain strengths which lends it to specific applications. Each of these systems has problems which limit its effectiveness.

Some real world patterns are purely statistical in nature. Statistical and probabilistic pattern recognition works by expecting data to exhibit statistical patterns. Pattern recognition by this method alone is limited. Statistical pattern recognizers cannot see beyond the expected statistical pattern. Only the expected statistical pattern can be detected.

Syntactic pattern recognizers function by expecting data to exhibit structure. While syntactic pattern recognizers are an improvement over statistical pattern recognizers, perception is still narrow and the system cannot perceive beyond the expected structures. While some real world patterns are structural in nature, the extraction of structure is unreliable.

Pattern recognition systems that rely upon neural pattern recognizers are an improvement over statistical and syntactic recognizers. Neural recognizers operate by storing training patterns as synaptic weights. Later stimulation retrieves these patterns and classifies the data. However, the fixed structure of neural pattern recognizers limits their scope of recognition. While a neural system can learn on its own, it can only find the patterns that its fixed structure allows it to see. The difficulties with this fixed structure are illustrated by the well-known problem that the number of hidden layers in a neural network strongly affects its ability to learn and generalize. Additionally, neural pattern recognition results are often not reproducible. Neural nets are also sensitive to training order, often require redundant data for training, can be slow learners and sometimes never learn. Most importantly, as with statistical and syntactic pattern recognition systems, neural pattern recognition systems are incapable of discovering truly new knowledge.

Accordingly, there is a need for an improved method and apparatus for pattern recognition, analysis, and classification which is not encumbered by preconceptions about data or models.

## BRIEF SUMMARY OF THE INVENTION

By way of illustration only, an analyzer/classifier process for data comprises using energy minimization with one or more input matrices. The data to be analyzed/classified is processed by an energy minimization technique such as individual differences multidimensional scaling (IDMDS) to produce at least a rate of change of stress/energy. Using the rate of change of stress/energy and possibly other IDMDS output, the data are analyzed or classified through patterns recognized within the data. The foregoing discussion of one embodiment has been presented only by way of introduction. Nothing in this section should be taken as a limitation on the following claims, which define the scope of the invention.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a diagram illustrating components of an analyzer according to the first embodiment of the invention; and

FIG. 2 through FIG. 10 relate to examples illustrating use of an embodiment of the invention for data classification, pattern recognition, and signal processing.

## DETAILED DESCRIPTION THE PRESENTLY PREFERRED EMBODIMENTS

The method and apparatus in accordance with the present invention provide an analysis tool with many applications. This tool can be used for data classification, pattern recognition, signal processing, sensor fusion, data compression, network reconstruction, and many other purposes. The invention relates to a general method for data analysis based on energy minimization and least energy deformations. The invention uses energy minimization principles to analyze one to many data sets. As used herein, energy is a convenient descriptor for concepts which are handled similarly mathematically. Generally, the physical concept of energy is not intended by use of this term but the more general mathematical concept. Within multiple data sets, individual data sets are

characterized by their deformation under least energy merging. This is a contextual characterization which allows the invention to exhibit integrated unsupervised learning and generalization. A number of methods for producing energy minimization and least energy merging and extraction of deformation information have been identified; these include, the finite element method (FEM), simulated annealing, and individual differences multidimensional scaling (IDMDS). The presently preferred embodiment of the invention utilizes individual differences multidimensional scaling (IDMDS).

Multidimensional scaling (MDS) is a class of automated, numerical techniques for converting proximity data into geometric data. IDMDS is a generalization of MDS, which converts multiple sources of proximity data into a common geometric configuration space, called the common space, and an associated vector space called the source space. Elements of the source space encode deformations of the common space specific to each source of proximity data. MDS and IDMDS were developed for psychometric research, but are now standard tools in many statistical software packages. MDS and IDMDS are often described as data visualization techniques. This description emphasizes only one aspect of these algorithms.

Broadly, the goal of MDS and IDMDS is to represent proximity data in a low dimensional metric space. This has been expressed mathematically by others (see, for example, de Leeuw, J. and Heiser, W., "Theory of multidimensional scaling," in P. R. Krishnaiah and L. N. Kanal, eds., *Handbook of Statistics*, Vol. 2. North-Holland, New York, 1982) as follows. Let  $S$  be a nonempty finite set,  $p$  a real valued function on  $S \times S$ ,

$$p : S \times S \rightarrow \mathbf{R}.$$

$p$  is a measure of proximity between objects in  $S$ . Then the goal of MDS is to construct a mapping  $\tilde{f}$  from  $S$  into a metric space  $(X, d)$ ,

$$\tilde{f} : S \rightarrow X,$$

such that  $p(i, j) = p_y \approx d(\tilde{f}(i), \tilde{f}(j))$ , that is, such that the proximity of object  $i$  to object  $j$  in  $S$  is approximated by the distance in  $X$  between  $\tilde{f}(i)$  and  $\tilde{f}(j)$ .  $X$  is usually assumed to be  $n$  dimensional Euclidean space  $\mathbf{R}^n$ , with  $n$  sufficiently small.

IDMDS generalizes MDS by allowing multiple sources. For  $k = 1, \dots, m$  let  $S_k$  be a finite set with proximity measure  $p_k$ , then IDMDS constructs maps

$$\tilde{f}_k : S_k \rightarrow X$$

such that  $p_k(i, j) = p_{yk} \approx d(\tilde{f}_k(i), \tilde{f}_k(j))$ , for  $k = 1, \dots, m$ .

Intuitively, IDMDS is a method for representing many points of view. The different proximities  $p_k$  can be viewed as giving the proximity perceptions of different judges. IDMDS accommodates these different points of view by finding different maps  $\tilde{f}_k$  for each judge. These individual maps, or their image configurations, are deformations of a common configuration space whose interpoint distances represent the common or merged point of view.

MDS and IDMDS can equivalently be described in terms of transformation functions. Let  $P = (p_y)$  be the matrix defined by the proximity  $p$  on  $S \times S$ . Then MDS defines a transformation function

$$f : p_y \mapsto d_y(X),$$

where  $d_y(X) = d(\tilde{f}(i), \tilde{f}(j))$ , with  $\tilde{f}$  the mapping from  $S \rightarrow X$  induced by the transformation function  $f$ . Here, by abuse of notation,  $X = \tilde{f}(S)$ , also denotes the image of  $S$  under  $\tilde{f}$ . The transformation function  $f$  should be optimal in the sense that the distances  $f(p_y)$  give the best approximation to the proximities  $p_y$ . This optimization criterion is described in more detail below. IDMDS is similarly re-

expressed; the single transformation  $f$  is replaced by  $m$  transformations  $f_k$ . Note, these  $f_k$  need not be distinct. In the following, the image of  $S_k$  under  $f_k$  will be written  $X_k$ .

MDS and IDMDS can be further broken down into so-called metric and nonmetric versions. In metric MDS or IDMDS, the transformations  $f(f_k)$  are parametric functions of the proximities  $p_{ij}(p_{ijk})$ . Nonmetric MDS or IDMDS generalizes the metric approach by allowing arbitrary admissible transformations  $f(f_k)$ , where admissible means the association between proximities and transformed proximities (also called disparities in this context) is weakly monotone:

$$p_{ij} < p_{kl} \text{ implies } f(p_{ij}) \leq f(p_{kl}).$$

Beyond the metric-nonmetric distinction, algorithms for MDS and IDMDS are distinguished by their optimization criteria and numerical optimization routines. One particularly elegant and publicly available IDMDS algorithm is PROXSCAL. See Commandeur, J. and Heiser, W., "Mathematical derivations in the proximity scaling (PROXSCAL) of symmetric data matrices," *Tech. report no. RR-93-03*, Department of Data Theory, Leiden University, Leiden, The Netherlands. PROXSCAL is a least squares, constrained majorization algorithm for IDMDS. We now summarize this algorithm, following closely the above reference.

PROXSCAL is a least squares approach to IDMDS which minimizes the objective function

$$\sigma(f_1, \dots, f_m, X_1, \dots, X_m) = \sum_{k=1}^m \sum_{i < j}^n w_{ijk} (f_k(p_{ijk}) - d_{ij}(X_k))^2.$$

$\sigma$  is called the stress and measures the goodness-of-fit of the configuration distances  $d_{ij}(X_k)$  to the transformed proximities  $f_k(p_{ijk})$ . This is the most general form for the objective function. MDS can be interpreted as an energy minimization process and stress can be interpreted as an energy functional. The  $w_{ijk}$  are proximity weights. For simplicity, it is assumed in what follows that  $w_{ijk} = 1$  for all  $i, j, k$ .

The PROXSCAL majorization algorithm for MDS with transformations is summarized as follows.

1. Choose a (possibly random) initial configuration  $X^0$ .
2. Find optimal transformations  $f(p_{ij})$  for fixed distances  $d_{ij}(X^0)$ .
3. Compute the initial stress

$$\sigma(f, X^0) = \sum_{i < j}^n (f(p_{ij}) - d_{ij}(X^0))^2.$$

4. Compute the Guttman transform  $\bar{X}$  of  $X^0$  with the transformed proximities  $f(p_{ij})$ . This is the majorization step.
5. Replace  $X^0$  with  $\bar{X}$  and find optimal transformations  $f(p_{ij})$  for fixed distances  $d_{ij}(X^0)$ .
6. Compute  $\sigma(f, X^0)$ .
7. Go to step 4 if the difference between the current and previous stress is not less than  $\varepsilon$ , some previously defined number. Stop otherwise.

For multiple sources of proximity data, restrictions are imposed on the configurations  $X_k$  associated to each source of proximity data in the form of the constraint equation  $X_k = ZW_k$ .

This equation defines a common configuration space  $Z$  and diagonal weight matrices  $W_k$ .  $Z$  represents a merged or common version of the input sources, while the  $W_k$  define the deformation of the common space required to produce the

individual configurations  $X_k$ . The vectors defined by  $\text{diag}(W_k)$ , the diagonal entries of the weight matrices  $W_k$ , form the source space  $W$  associated to the common space  $Z$ .

The PROXSCAL constrained majorization algorithm for IDMDS with transformations is summarized as follows. To simplify the discussion, so-called unconditional IDMDS is described. This means the  $m$  transformation functions are the same:  $f_1 = f_2 = \dots = f_m$ .

1. Choose constrained initial configurations  $X_k^0$ .
2. Find optimal transformations  $f(p_{ijk})$  for fixed distances  $d_{ij}(X_k^0)$ .
3. Compute the initial stress

$$\sigma(f, X_1^0, \dots, X_m^0) = \sum_{k=1}^m \sum_{i < j}^n (f(p_{ijk}) - d_{ij}(X_k^0))^2.$$

4. Compute unconstrained updates  $\bar{X}_k$  of  $X_k^0$  using the Guttman transform with transformed proximities  $f(p_{ijk})$ . This is the unconstrained majorization step.
5. Solve the metric projection problem by finding  $X_k^+$  minimizing

$$h(X_1, \dots, X_m) = \sum_{k=1}^m \text{tr} (X_k - \bar{X}_k)' (X_k - \bar{X}_k)$$

subject to the constraints  $X_k = ZW_k$ . This step constrains the updated configurations from step 4.

6. Replace  $X_k^0$  with  $X_k^+$  and find optimal transformations  $f(p_{ijk})$  for fixed distances  $d_{ij}(X_k^0)$ .
7. Compute  $\sigma(f, X_1^0, \dots, X_m^0)$ .

8. Go to step 4 if the difference between the current and previous stress is not less than  $\varepsilon$ , some previously defined number. Stop otherwise.

Here,  $\text{tr}(A)$  and  $A'$  denote, respectively, the trace and transpose of matrix  $A$ .

5 It should be pointed out that other IDMDS routines do not contain an explicit constraint condition. For example, ALSCAL (see Takane, Y., Young, F, and de Leeuw, J., "Nonmetric individual differences multidimensional scaling: an alternating least squares method with optimal scaling features," *Psychometrika*, Vol. 42, 1977) minimizes a different energy expression (sstress) over  
10 transformations, configurations, and weighted Euclidean metrics. ALSCAL also produces common and source spaces, but these spaces are computed through alternating least squares without explicit use of constraints. Either form of IDMDS can be used in the present invention.

MDS and IDMDS have proven useful for many kinds of analyses.  
15 However, it is believed that prior utilizations of these techniques have not extended the use of these techniques to further possible uses for which MDS and IDMDS have particular utility and provide exceptional results. Accordingly, one benefit of the present invention is to incorporate MDS or IDMDS as part of a platform in which aspects of these techniques are extended. A further benefit is to  
20 provide an analysis technique, part of which uses IDMDS, that has utility as an analytic engine applicable to problems in classification, pattern recognition, signal processing, sensor fusion, and data compression, as well as many other kinds of data analytic applications.

Referring now to FIG. 1, it illustrates an operational block diagram of a  
25 data analysis/classifier tool 100. The least energy deformation analyzer/classifier is a three-step process. Step 110 is a front end for data transformation. Step 120 is a process step implementing energy minimization and deformation computations—in the presently preferred embodiment, this process step is implemented through the IDMDS algorithm. Step 130 is a back end which

interprets or decodes the output of the process step 120. These three steps are illustrated in FIG. 1.

It is to be understood that the steps forming the tool 100 may be implemented in a computer usable medium or in a computer system as computer executable software code. In such an embodiment, step 110 may be configured as a code, step 120 may be configured as second code and step 130 may be configured as third code, with each code comprising a plurality of machine readable steps or operations for performing the specified operations. While step 110, step 120 and step 130 have been shown as three separate elements, their functionality can be combined and/or distributed. It is to be further understood that "medium" is intended to broadly include any suitable medium, including analog or digital, hardware or software, now in use or developed in the future.

Step 110 of the tool 100 is the transformation of the data into matrix form. The only constraint on this transformation for the illustrated embodiment is that the resulting matrices be square. The type of transformation used depends on the data to be processed and the goal of the analysis. In particular, it is not required that the matrices be proximity matrices in the traditional sense associated with IDMDS. For example, time series and other sequential data may be transformed into source matrices through straight substitution into entries of symmetric matrices of sufficient dimensionality (this transformation will be discussed in more detail in an example below). Time series or other signal processing data may also be Fourier or otherwise analyzed and then transformed to matrix form.

Step 120 of the tool 100 implements energy minimization and extraction of deformation information through IDMDS. In the IDMDS embodiment of the tool 100, the stress function  $\sigma$  defines an energy functional over configurations and transformations. The configurations are further restricted to those which satisfy the constraint equations  $X_k = ZW_k$ . For each configuration  $X_k$ , the weight vectors  $\text{diag}(W_k)$  are the contextual signature, with respect to the common space, of the  $k$ -th input source. Interpretation of  $\sigma$  as an energy functional is

fundamental; it greatly expands the applicability of MDS as an energy minimization engine for data classification and analysis.

Step 130 consists of both visual and analytic methods for decoding and interpreting the source space  $W$  from step 120. Unlike traditional applications of IDMDS, tool 100 often produces high dimensional output. Among other things, this makes visual interpretation and decoding of the source space problematic. Possible analytic methods for understanding the high dimensional spaces include, but are not limited to, linear programming techniques for hyperplane and decision surface estimation, cluster analysis techniques, and generalized gravitational model computations. A source space dye-dropping or tracer technique has been developed for both source space visualization and analytic postprocessing. Step 130 may also consist in recording stress/energy, or the rate of change of stress/energy, over multiple dimensions. The graph of energy (rate or change or stress/energy) against dimension can be used to determine network and dynamical system dimensionality. The graph of stress/energy against dimensionality is traditionally called a scree plot. The use and purpose of the scree plot is greatly extended in the present embodiment of the tool 100.

Let  $S = \{S_k\}$  be a collection of data sets or sources  $S_k$  for  $k = 1, \dots, m$ . Step 110 of the tool 100 converts each  $S_k \in S$  to matrix form  $M(S_k)$  where  $M(S_k)$  is a  $p$  dimensional real hollow symmetric matrix. Hollow means the diagonal entries of  $M(S_k)$  are zero. As indicated above,  $M(S_k)$  need not be symmetric or hollow, but for simplicity of exposition these additional restrictions are adopted. Note also that the matrix dimensionality  $p$  is a function of the data  $S$  and the goal of the analysis. Since  $M(S_k)$  is hollow symmetric, it can be interpreted and processed in IDMDS as a proximity (dissimilarity) matrix. Step 110 can be represented by the map

$$M : S \rightarrow H^p(\mathbf{R}),$$

$$S_k \mapsto M(S_k)$$

where  $H^p(\mathbf{R})$  is the set of  $p$  dimensional hollow real symmetric matrices. The precise rule for computing  $M$  depends on the type of data in  $S$ , and the purpose of the analysis. For example, if  $S$  contains time series data, then  $M$  might entail the straightforward entry-wise encoding mentioned above. If  $S$  consists of optical character recognition data, or some other kind of geometric data, then  $M(S_k)$  may be a standard distance matrix whose  $ij$ -th entry is the Euclidean distance between "on" pixels  $i$  and  $j$ .  $M$  can also be combined with other transformations to form the composite,  $(M \circ F)(S_k)$ , where  $F$ , for example, is a fast Fourier transform (FFT) on signal data  $S_k$ . To make this more concrete, in the examples below  $M$  will be explicitly calculated in a number of different ways. It should also be pointed out that for certain data collections  $S$  it is possible to analyze the conjugate or transpose  $S'$  of  $S$ . For instance, in data mining applications, it is useful to transpose records (clients) and fields (client attributes) thus allowing analysis of attributes as well as clients. The mapping  $M$  is simply applied to the transposed data.

Step 120 of the presently preferred embodiment of the tool 100 is the application of IDMDS to the set of input matrices  $M(S) = \{M(S_k)\}$ . Each  $M(S_k) \in M(S)$  is an input source for IDMDS. As described above, the IDMDS output is a common space  $Z \subset \mathbf{R}^n$  and a source space  $\mathcal{W}$ . The dimensionality  $n$  of these spaces depends on the input data  $S$  and the goal of the analysis. For signal data, it is often useful to set  $n = p - 1$  or even  $n = |S_k|$  where  $|S_k|$  denotes the cardinality of  $S_k$ . For data compression, low dimensional output spaces are essential. In the case of network reconstruction, system dimensionality is discovered by the invention itself.

IDMDS can be thought of as a constrained energy minimization process. As discussed above, the stress  $\sigma$  is an energy functional defined over transformations and configurations in  $\mathbf{R}^n$ ; the constraints are defined by the constraint equation  $X_k = ZW_k$ . IDMDS attempts to find the lowest stress or energy configurations  $X_k$  which also satisfy the constraint equation. (MDS is the

special case when each  $W_k = I$ , the identity matrix.) Configurations  $X_k$  most similar to the source matrices  $M(S_k)$  have the lowest energy. At the same time, each  $X_k$  is required to match the common space  $Z$  up to deformation defined by the weight matrices  $W_k$ . The common space serves as a characteristic, or

5 reference object. Differences between individual configurations are expressed in terms of this characteristic object with these differences encoded in the weight matrices  $W_k$ . The deformation information contained in the weight matrices, or, equivalently, in the weight vectors defined by their diagonal entries, becomes the signature of the configurations  $X_k$  and hence the sources  $S_k$  (through  $M(S_k)$ ).

10 The source space may be thought of as a signature classification space.

The weight space signatures are contextual; they are defined with respect to the reference object  $Z$ . The contextual nature of the source deformation signature is fundamental. As the polygon classification example below will show,  $Z$ -contextuality of the signature allows the tool 100 to display integrated

15 unsupervised machine learning and generalization. The analyzer/classifier learns seamlessly and invisibly.  $Z$ -contextuality also allows the tool 100 to operate without a priori data models. The analyzer/classifier constructs its own model of the data, the common space  $Z$ .

Step 130, the back end of the tool 100, decodes and interprets the source or

20 classification space output  $W$  from IDMDS. Since this output can be high dimensional, visualization techniques must be supplemented by analytic methods of interpretation. A dye-dropping or tracer technique has been developed for both visual and analytic postprocessing. This entails differential marking or coloring of source space output. The specification of the dye-dropping is contingent upon the

25 data and overall analysis goals. For example, dye-dropping may be two-color or binary allowing separating hyperplanes to be visually or analytically determined. For an analytic approach to separating hyperplanes using binary dye-dropping see Bosch, R. and Smith, J, "Separating hyperplanes and the authorship of the disputed federalist papers," *American Mathematical Monthly*, Vol. 105, 1998.

Discrete dye-dropping allows the definition of generalized gravitational clustering measures of the form

$$g_p(A, x) = \frac{\sum_{y \neq x} \chi_A(x) \exp(p \cdot d(x, y))}{\sum_{y \neq x} \exp(p \cdot d(x, y))}.$$

Here,  $A$  denotes a subset of  $W$  (indicated by dye-dropping),  $\chi_A(x)$ , is the characteristic function on  $A$ ,  $d(\cdot, \cdot)$  is a distance function, and  $p \in \mathbb{R}$ . Such measures may be useful for estimating missing values in data bases. Dye-dropping can be defined continuously, as well, producing a kind of height function on  $W$ . This allows the definition of decision surfaces or volumetric discriminators. The source space  $W$  is also analyzable using standard cluster analytic techniques. The precise clustering metric depends on the specifications and conditions of the IDMDS analysis in question.

Finally, as mentioned earlier, the stress/energy and rate of change of stress/energy can be used as postprocessing tools. Minima or kinks in a plot of energy, or the rate of change of energy, over dimension can be used to determine the dimensionality of complex networks and general dynamical systems for which only partial output information is available. In fact, this technique allows dimensionality to be inferred often from only a single data stream of time series of observed data.

A number of examples are presented below to illustrate the method and apparatus in accordance with the present invention. These examples are illustrative only and in no way limit the scope of the method or apparatus.

*Example A: Classification of regular polygons*

The goal of this experiment was to classify a set of regular polygons. The collection  $S = \{S_1, \dots, S_{16}\}$  with data sets  $S_1 - S_4$ , equilateral triangles;  $S_5 - S_8$ , squares;  $S_9 - S_{12}$ , pentagons; and  $S_{13} - S_{16}$ , hexagons. Within each subset of distinct polygons, the size of the figures is increasing with the subscript. The perimeter of each polygon  $S_k$  was divided into 60 equal segments with the

segment endpoints ordered clockwise from a fixed initial endpoint. A turtle application was then applied to each polygon to compute the Euclidean distance from each segment endpoint to every other segment endpoint (initial endpoint included). Let  $x'_{s_k}$  denote the  $i$ -th endpoint of polygon  $S_k$ , then the mapping  $M$  is defined by

$$M : S \rightarrow H^{60}(R),$$

$$S_k \mapsto [d_{s_k^1} | d_{s_k^2} | \dots | d_{s_k^{60}}]$$

where the columns

$$d_{s_k^i} = (d(x'_{s_k}, x_{s_k}^1), d(x'_{s_k}, x_{s_k}^2), \dots, d(x'_{s_k}, x_{s_k}^{60}))'.$$

The individual column vectors  $d_{s_k^i}$  have intrinsic interest. When plotted as functions of arc length they represent a geometric signal which contains both frequency and spatial information.

The 16,  $60 \times 60$  distance matrices were input into a publicly distributed version of PROXSCAL. PROXSCAL was run with the following technical specifications: sources- 16, objects- 60, dimension- 4, model- weighted, initial configuration- Torgerson, conditionality- unconditional, transformations- numerical, rate of convergence- 0.0, number of iterations- 500, and minimum stress- 0.0.

FIG. 2 and FIG. 3 show the four dimensional common and source space output. The common space configuration appears to be a multifaceted representation of the original polygons. It forms a simple closed path in four dimensions which, when viewed from different angles, or, what is essentially the same thing, when deformed by the weight matrices, produces a best, in the sense of minimal energy, representation of each of the two dimensional polygonal

figures. The most successful such representation appears to be that of the triangle projected onto the plane determined by dimensions 2 and 4.

In the source space, the different types of polygons are arranged, and hence, classified, along different radii. Magnitudes within each such radial classification indicate polygon size or scale with the smaller polygons located nearer the origin.

The contextual nature of the polygon classification is embodied in the common space configuration. Intuitively, this configuration looks like a single, carefully bent wire loop. When viewed from different angles, as encoded by the source space vectors, this loop of wire looks variously like a triangle, a square, a pentagon, or a hexagon.

Example B: Classification of non-regular polygons

The polygons in Example A were regular. In this example, irregular polygons  $S = \{S_1, \dots, S_6\}$  are considered, where  $S_1 - S_3$  are triangles and  $S_4 - S_6$  rectangles. The perimeter of each figure  $S_k$  was divided into 30 equal segments with the preprocessing transformation  $M$  computed as in Example A. This produced 6,  $30 \times 30$  source matrices which were input into PROXSCAL with technical specifications the same as those above except for the number of sources, 6, and objects, 30.

FIG. 4 and FIG. 5 show the three dimensional common and source space outputs. The common space configuration, again, has a "holographic" or faceted quality; when illuminated from different angles, it represents each of the polygonal figures. As before, this change of viewpoint is encoded in the source space weight vectors. While the weight vectors encoding triangles and rectangles are no longer radially arranged, they can clearly be separated by a hyperplane and are thus accurately classified by the analysis tool as presently embodied.

It is notable that two dimensional IDMDS outputs were not sufficient to classify these polygons in the sense that source space separating hyperplanes did not exist in two dimensions.

Example C: Time series data

This example relates to signal processing and demonstrates the analysis tool's invariance with respect to phase and frequency modification of time series data. It also demonstrates an entry-wise approach to computing the preprocessing transformation  $M$ .

The set  $S = \{S_1, \dots, S_{12}\}$  consisted of sine, square, and sawtooth waveforms. Four versions of each waveform were included, each modified for frequency and phase content. Indices 1-4 indicate sine, 5-8 square, and 9-12 sawtooth frequency and phase modified waveforms. All signals had unit amplitude and were sampled at 32 equal intervals  $x$ , for  $0 \leq x \leq 2\pi$ .

Each time series  $S_k$  was mapped into a symmetric matrix as follows. First, an "empty" nine dimensional, lower triangular matrix  $T_k = (t_{ij}^k) = T(S_k)$  was created. "Empty" meant that  $T_k$  had no entries below the diagonal and zeros everywhere else. Nine dimensions were chosen since nine is the smallest positive integer  $m$  satisfying the inequality  $m(m-1)/2 \geq 32$  and  $m(m-1)/2$  is the number of entries below the diagonal in an  $m$  dimensional matrix. The empty entries in  $T_k$  were then filled in, from upper left to lower right, column by column, by reading in the time series data from  $S_k$ . Explicitly:  $s_1^k = t_{21}^k$ , the first sample in  $S_k$  was written in the second row, first column of  $T_k$ ;  $s_2^k = t_{31}^k$ , the second sample in  $S_k$  was written in the third row, first column of  $T_k$ , and so on. Since there were only 32 signal samples for 36 empty slots in  $T_k$ , the four remaining entries were designated missing by writing -2 in these positions (These entries are then ignored when calculating the stress). Finally, a hollow symmetric matrix was defined by setting

$$M(S_k) = T_k + T_k^t.$$

This preprocessing produced 12,  $9 \times 9$  source matrices which were input to PROXSCAL with the following technical specifications: sources- 12, objects- 9,

dimension- 8, model- weighted, initial configuration- Torgerson, conditionality- unconditional, transformations- ordinal, approach to ties- secondary, rate of convergence- 0.0, number of iterations- 500, and minimum stress- 0.0. Note that the data, while metric or numeric, was transformed as if it were ordinal or nonmetric. The use of nonmetric IDMDS has been greatly extended in the present embodiment of the tool 100.

FIG. 6 shows the eight dimensional source space output for the time series data. The projection in dimensions seven and eight, as detailed in FIG. 7, shows the input signals are separated by hyperplanes into sine, square, and sawtooth waveform classes independent of the frequency or phase content of the signals.

Example D: Sequences, Fibonacci, etc.

The data set  $S = \{S_1, \dots, S_9\}$  in this example consisted of nine sequences with ten elements each; they are shown in Table 1, FIG. 8. Sequences 1-3 are constant, arithmetic, and Fibonacci sequences respectively. Sequences 4-6 are these same sequences with some error or noise introduced. Sequences 7-9 are the same as 1-3, but the negative 1's indicate that these elements are missing or unknown.

The nine source matrices  $M(S_k) = (m_{ij}^k)$  were defined by

$$m_{ij}^k = |s_i^k - s_j^k|,$$

the absolute value of the difference of the  $i$ -th and  $j$ -th elements in sequence  $S_k$ .

The resulting  $10 \times 10$  source matrices were input to PROXSCAL configured as follows: sources- 9, objects- 10, dimension- 8, model- weighted, initial configuration- simplex, conditionality- unconditional, transformations- numerical, rate of convergence- 0.0, number of iterations- 500, and minimum stress- 0.0.

FIG. 9 shows dimensions 5 and 6 of the eight dimensional source space output. The sequences are clustered, hence classified, according to whether they are constant, arithmetic, or Fibonacci based. Note that in this projection, the constant sequence and the constant sequence with missing element coincide,

therefore only two versions of the constant sequence are visible. This result demonstrates that the tool 100 of the presently preferred embodiment can function on noisy or error containing, partially known, sequential data sets.

Example E: Missing value estimation for bridges

This example extends the previous result to demonstrate the applicability of the analysis tool to missing value estimation on noisy, real-world data. The data set consisted of nine categories of bridge data from the National Bridge Inventory (NBI) of the Federal Highway Administration. One of these categories, bridge material (steel or concrete), was removed from the database. The goal was to repopulate this missing category using the technique of the presently preferred embodiment to estimate the missing values.

One hundred bridges were arbitrarily chosen from the NBI. Each bridge defined an eight dimensional vector of data with components the NBI categories. These vectors were preprocessed as in Example D, creating one hundred  $8 \times 8$  source matrices. The matrices were submitted to PROXSCAL with specifications: sources- 100, objects- 8, dimension- 7, model- weighted, initial configuration- simplex, conditionality- unconditional, transformations- numerical, rate of convergence- 0.0, number of iterations- 500, and minimum stress- 0.00001.

The seven dimensional source space output was partially labeled by bridge material—an application of dye-dropping—and analyzed using the following function

$$g_p(A_i, x) = \frac{\sum_{y \neq x} \chi_{A_i}(x) \cdot d(x, y)^{-p}}{\sum_{y \neq x} d(x, y)^{-p}}$$

where  $p$  is an empirically determined negative number,  $d(x, y)$  is Euclidean distance on the source space, and  $\chi_{A_i}$  is the characteristic function on material set  $A_i$ ,  $i = 1, 2$ , where  $A_1$  is steel,  $A_2$  concrete. (For the bridge data, no two bridges had the same source space coordinates, hence  $g_p$  was well-defined.) A bridge

was determined to be steel (concrete) if  $g_p(A_1, x) > g_p(A_2, x)$   
 $(g_p(A_1, x) < g_p(A_2, x))$ . The result was indeterminate in case of equality.

The tool 100 illustrated in FIG. 1 estimated bridge construction material  
 with 90 percent accuracy.

5      Example F: Network dimensionality for a 4-node network

This example demonstrates the use of stress/energy minima to determine  
 network dimensionality from partial network output data. Dimensionality, in this  
 example, means the number of nodes in a network.

10      A four-node network was constructed as follows: generator nodes 1 to 3  
 were defined by the sine functions,  $\sin(2x)$ ,  $\sin(2x + \frac{\pi}{2})$ , and  $\sin(2x + \frac{4\pi}{3})$ ; node 4  
 was the sum of nodes 1 through 3. The output of node 4 was sampled at 32 equal  
 intervals between 0 and  $2\pi$ .

15      The data from node 4 was preprocessed in the manner of Example D: the  
 $ij$ -th entry of the source matrix for node 4 was defined to be the absolute value of  
 the difference between the  $i$ -th and  $j$ -th samples of the node 4 time series. A  
 second, reference, source matrix was defined using the same preprocessing  
 technique, now applied to thirty two equal interval samples of the function  $\sin(x)$   
 for  $0 \leq x \leq 2\pi$ . The resulting  $2, 32 \times 32$  source matrices were input to  
 20      PROXSCAL with technical specification: sources- 2, objects- 32, dimension- 1 to  
 6, model- weighted, initial configuration- simplex, conditionality- conditional,  
 transformations- numerical, rate of convergence- 0.0, number of iterations- 500,  
 and minimum stress- 0.0. The dimension specification had a range of values, 1 to  
 6. The dimension resulting in the lowest stress/energy is the dimensionality of the  
 underlying network.

25      Table 2, FIG. 10, shows dimension and corresponding stress/energy values  
 from the analysis by the tool 100 of the 4-node network. The stress/energy  
 minimum is achieved in dimension 4, hence the tool 100 has correctly determined  
 network dimensionality. Similar experiments were run with more sophisticated  
 dynamical systems and networks. Each of these experiments resulted in the  
 30      successful determination of system degrees of freedom or dimensionality. These

experiments included the determination of the dimensionality of a linear feedback shift register. These devices generate pseudo-random bit streams and are designed to conceal their dimensionality.

From the foregoing, it can be seen that the illustrated embodiment of the present invention provides a method and apparatus for classifying input data. Input data are received and formed into one or more matrices. The matrices are processed using IDMDS to produce a stress/energy value, a rate or change of stress/energy value, a source space and a common space. An output or back end process uses analytical or visual methods to interpret the source space and the common space. The technique in accordance with the present invention therefore avoids limitations associated with statistical pattern recognition techniques, which are limited to detecting only the expected statistical pattern, and syntactical pattern recognition techniques, which cannot perceive beyond the expected structures. Further, the tool in accordance with the present invention is not limited to the fixed structure of neural pattern recognizers. The technique in accordance with the present invention locates patterns in data without interference from preconceptions of models or users about the data. The pattern recognition method in accordance with the present invention uses energy minimization to allow data to self-organize, causing structure to emerge. Furthermore, the technique in accordance with the present invention determines the dimension of dynamical systems from partial data streams measured on those systems through calculation of stress/energy or rate of change of stress/energy across dimensions.

While a particular embodiment of the present invention has been shown and described, modifications may be made. For example, PROXSCAL may be replaced by other IDMDS routines which are commercially available or are proprietary. It is therefore intended in the appended claims to cover all such changes and modifications which fall within the true spirit and scope of the invention.

## CLAIMS

1. A method for classifying data, the method comprising the steps of:  
receiving input data for classification;  
5 defining one or more transformations of the input data;  
applying energy minimization to the one or more transforms of the input  
data;  
producing at least a rate of change in energy in response to energy  
minimization; and  
10 classifying the input data using at least the stress rate value.

2. The method of claim 1 wherein the step of applying energy  
minimization comprises using individual differences multidimensional scaling  
applied to the input data.

3. The method of claim 1 wherein the step of applying energy  
minimization comprises using a finite element method analysis applied to the  
input data.

4. The method of claim 1 wherein the step of applying energy  
minimization comprises using simulated annealing applied to the input data.

5. The method of claim 2 further comprising the steps of producing a  
source space output and classifying the input data using the source space output.

6. The method of claim 2 further comprising the steps of producing a  
common space output and classifying the input data using the common space  
output.

7. A classifier process for data comprising:  
using individual differences multidimensional scaling with one or more  
input proximity matrices into which the data to be classified has  
been converted to produce at least a source space output; and  
5 using the source space output to classify the data.

8. The invention of claim 7 further comprising the step of:  
prior to the step of using individual differences multidimensional scaling,  
producing the one or more proximity matrices from the data to be  
10 classified.

9. The invention of claim 7 wherein said step of using individual  
differences multidimensional scaling also produces a common space output, and  
wherein the classifier process further comprises the step of:  
15 additionally using the common space output to classify the data.

10. The invention of claim 7 wherein said step of using the source space  
output to classify the data, is further characterized as comprising the step of:  
searching for clustering.  
20

11. The invention of claim 7 wherein said step of using the source space  
output to classify the data, is further characterized as comprising the step of:  
searching for hyperplane discriminators.

12. The invention of claim 7 wherein said step of using the source space  
output to classify the data, is further characterized as comprising the step of:  
searching for decision surfaces.  
25

13. The invention of claim 7 wherein said step of using the source space  
output to classify the data, is further characterized as comprising the step of:  
searching for classifying structures.  
30

14. A classifier process for data comprising:  
using individual differences multidimensional scaling with one or more  
input proximity matrices into which the data to be classified has  
been converted to produce at least a source space output; and  
using the source space output for pattern recognition.

15. A classifier process for data comprising:  
using individual differences multidimensional scaling with one or more  
input proximity matrices into which the data to be classified has  
been converted to produce at least a source space output; and  
using the source space output for sensor fusion.

16. A method for optical character recognition comprising:  
using individual differences multidimensional scaling with one or more  
input proximity matrices into which the data including the  
characters to be recognized has been converted to produce at least a  
source space output; and  
using the source space output for optical character recognition.

17. A method for data compression comprising:  
using individual differences multidimensional scaling with one or more  
input proximity matrices into which the data to be compressed has  
been converted to produce at least a source space output; and  
using the source space output for data compression.

18. A method for data compression comprising:  
producing the one or more proximity matrices including the data to be  
compressed;

using individual differences multidimensional scaling upon the one or more  
input proximity matrices to produce a source space output and a  
common space output; and  
using the source space output and the common space output as a  
compressed representation of the data.

19. A data compression method for data comprising:  
using individual differences multidimensional scaling with one or more  
input proximity matrices into which the data to be compressed has  
been converted to produce a common space output and a source  
space output; and  
transferring the common space output and the source space output as a  
compressed representation of the data.

20. A program for classifying data comprised of:  
a first program portion that uses individual differences multidimensional  
scaling with one or more input proximity matrices into which the  
data to be classified has been converted to produce at least a source  
space output;  
a second program portion that uses the source space output to classify the  
data.

21. A program for classifying data comprised of:  
a first program portion that using individual differences multidimensional  
scaling with one or more input proximity matrices into which the  
data to be classified has been converted to produce at least a source  
space output;  
a second program portion that performs an analysis of the source space  
output; and  
a third program portion that classifies the data based upon the analysis  
performed by the second program portion.

22. Computer executable software code stored on a computer readable  
medium, the code for classifying input data, the code comprising:  
first code that receives the input data and forms one or more matrices using  
the input data;  
second code that applies individual differences multidimensional scaling to  
the one or more matrices and produces at least a source space; and  
third code that uses the source space to classify the input data according to  
one or more predetermined criteria and produce output data  
representative of data classification.

23. The computer executable software code of claim 22 wherein the  
first code forms one or more square matrices.

24. The computer executable software code of claim 22 wherein the  
first code forms one or more hollow, symmetric matrices.

25. The computer executable software code of claim 22 wherein the  
input data are time series data and wherein each element of the one or more  
matrices is a datum from the time series data.

26. The computer executable software code of claim 22 wherein the second code further produces a common space, the third code using both the source space and the common space for classifying the input data.

5 27. The computer executable software code of claim 22 wherein the second code performs an energy minimization process.

28. The computer executable software code of claim 27 wherein the second code defines a stress  $\sigma$  over configurations of the input data and finds a configuration  $X_{SK}$  having a lowest stress.

29. The computer executable software code of claim 28 wherein the second code defines a constraint equation  $X_k = ZW_k$  and wherein the second code finds the configuration  $X_k$  which also satisfies a constraint equation.

30. The computer executable software code of claim 22 wherein the third code searches for clustering of elements of the source space.

31. The computer executable software code of claim 22 wherein the third code searches for hyperplane discriminators of the source space.

32. A signal processing method comprising the steps of:  
receiving input data representative of time varying signals;  
mapping the input data into one or more matrices;  
applying individual differences multidimensional scaling to the one or  
more matrices to produce a source space output; and  
processing the input data using the source space output.

33. The signal processing method of claim 32 wherein processing the  
input data comprises separating elements of the source space output using  
hyperplanes.

34. A signal processing method comprising the steps of:  
receiving input data representative of time varying signals;  
mapping the input data into one or more matrices;  
applying individual differences multidimensional scaling to the one or  
more matrices to produce a common space output; and  
processing the input data using the common space output.

35. The signal processing method of claim 32 wherein processing the  
input data comprises separating elements of the common space output using  
hyperplanes.

36. A signal processing method comprising the steps of:  
receiving input data representative of time varying signals;  
mapping the input data into one or more matrices;  
applying individual differences multidimensional scaling to the one or  
more matrices to produce a rate of change of stress/energy; and  
processing the input data using the rate of change of stress/energy.

37. A method for determining dimensionality of a network, the dimensionality corresponding to a number of degrees of freedom in the network, the method comprising the steps of:

sampling data from one or more nodes of the network;  
mapping the data into one or more matrices;  
applying individual differences multidimensional scaling to the one or more matrices to produce a stress/energy; and  
processing the stress/energy to determine the dimensionality of the network.

38. A method for determining dimensionality of a network, the dimensionality corresponding to a number of degrees of freedom in the network, the method comprising the steps of:

sampling data from one or more nodes of the network;  
mapping the data into one or more matrices;  
applying individual differences multidimensional scaling to the one or more matrices to produce a rate of change of stress/energy output and  
processing the rate of change of stress/energy output to determine the dimensionality of the network.

39. A method for determining dimensionality of a network, the dimensionality corresponding to a number of degrees of freedom in the network, the method comprising the steps of:

sampling data from one or more nodes of the network;  
mapping the data into one or more matrices;  
applying individual differences multidimensional scaling to the one or more matrices to produce a common space output; and  
processing the common space output to determine the dimensionality of the network.

40. A method for reconstructing a network, the method comprising the steps of

sampling data from one or more nodes of the network;

mapping the data into one or more matrices;

5 applying individual differences multidimensional scaling to the one or

more matrices to produce a source space output;

from the source space output, determining the dimensionality of the network;

using free nodes to recreate and reconstruct individual nodes through the

10 use of matrices containing missing values; and

establishing node connectivity through the use of lowest-energy

connections constrained by dimensionality.

41. A method for determining dimensionality of a dynamical system from partial data, the dimensionality corresponding to a number of degrees of freedom in the dynamical system, the method comprising the steps of:

15 sampling data from the dynamical system;

mapping the data into one or more matrices;

applying individual differences multidimensional scaling to the one or

20 more matrices to produce a stress/energy;

processing the stress/energy to determine dimensionality of the dynamical system.

42. A method for determining dimensionality of a dynamical system from partial data, the dimensionality corresponding to a number of degrees of freedom in the dynamical system, the method comprising the steps of:

sampling data from the dynamical system;

mapping the data into one or more matrices;

applying individual differences multidimensional scaling to the one or more matrices to produce rate of change of stress/energy output; processing the rate of change of stress/energy output to determine dimensionality of the dynamical system.

43. A method for determining dimensionality of a dynamical system from partial data, the dimensionality corresponding to a number of degrees of freedom in the dynamical system, the method comprising the steps of:

sampling data from the dynamical system;

mapping the data into one or more matrices;

applying individual differences multidimensional scaling to the one or more matrices to produce a common space output;

processing the common space output to determine dimensionality of the dynamical system.

### STEP 3. POSTPROCESSING SOURCE CODE

Mathematica code for step 3 of the invention: postprocessing.

Subfunctions:

(\* Euclidean distance between vectors u and v \*)

```
d[u_, v_] := Sqrt[(u - v) . (u - v)] // N;
```

(\* Characteristic function \*)

```
char[u_, x_] := If[x == u, 1, 0];
```

Clustering functions for back-end analysis of classifying space of invention:

```

g1[obj_, dyeval_, dyelist_, L1_, L2_, power_] := Plus@@Table[If[i == obj, 0,
char[dyeval, dyelist[[i]]] d[L1[[obj]], L2[[i]]] ^ (power)], {i, Length[dyelist]]} /
Plus@@
Table[If[i == obj, 0, d[L1[[obj]], L2[[i]]] ^ (power)], {i, Length[L2]}];

g2[obj_, dyeval_, dyelist_, L2_, power_] := Plus@@Table[If[i == obj, 0,
char[dyeval, dyelist[[i]]] d[L2[[obj]], L2[[i]]] ^ (power)], {i, Length[dyelist]]} /
Plus@@
Table[If[i == obj, 0, d[L2[[obj]], L2[[i]]] ^ (power)], {i, Length[L2]}];

g3[obj_, dyeval_, dyelist_, L2_, power_] :=
Plus@@Table[If[i == obj, 0, char[dyeval, dyelist[[i]]]
Exp[d[L2[[obj]], L2[[i]]] ^ (power)], {i, Length[dyelist]]} /
Plus@@
Table[If[i == obj, 0, Exp[d[L2[[obj]], L2[[i]]] ^ (power)], {i, Length[L2]}];

Case No. 9185/10**DECLARATION FOR PATENT APPLICATION**

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name.

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled ENERGY MINIMIZATION FOR CLASSIFICATION, PATTERN RECOGNITION, SENSOR FUSION, DATA COMPRESSION, NETWORK RECONSTRUCTION AND SIGNAL PROCESSING, the specification of which:

- ☒ is attached hereto.
- ☐ was filed on \_\_\_\_\_ as Application Serial No. \_\_\_\_\_.
- ☐ and was amended on \_\_\_\_\_ (if applicable)

I hereby state that I have reviewed and understand the contents of the above-identified specification including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the patentability as defined in Title 37, Code of Federal Regulations, § 1.56(a).

I hereby claim foreign priority benefits under 35 U.S.C. § 119(a)-(d) or § 365(b) of any foreign application(s) for patent or inventor's certificate or § 365(a) of any PCT International application which designated at least one country other than the United States, listed below and have also identified below, by checking the box, any foreign application for patent or inventor's certificate, or PCT International application having a filing date before that of the application on which priority is claimed
